Seminar 7 - Sequential Decision Problems, Bellman's equation, backward induction

Adrian Perez Keilty

Chalmers University of Technology, Göteborg, Sweden

Note: Check out the lower sections from the attached file

fpclimate.agda

for type-checking.

Exercise 7.1:

What are the types of head and measure in the definitions of sumR and val? Define head. How could the type of measure be generalized?

- head: From the use of (head xys) as the fourth argument in reward (reward t x y (head xys) ⊕ sumR xys), we can infer that the type of head is X t for a strictly positive t. Also, since head tipically refers to the first element of a list or vector, we can define head as the state belonging to the first pair of state-control pairs of a sequence XYSeq. We use an equivalent definition in Agda to the one defined in Idris presented in "On the Correctness of Monadic Backward Induction":

```
-- head: state of the first pair of XYseq head: {t n : Nat} \rightarrow XYSeq t (suc n) \rightarrow X t head (Last x) = x head ((x , y) || xys) = x
```

- measure: From the expression

val ps = measure o (fmapM sumR o trj ps)

measure takes in as input an element of type M Val and should return an element of type Val:

```
\texttt{measure} \; : \; \texttt{M} \; \; \texttt{Val} \; \to \; \texttt{Val}
```

In the general definition in vulnerability theory discussed earlier, we had

```
\texttt{measure} \; : \; \texttt{F} \; \; \texttt{V} \; \to \; \texttt{W}
```

where V was the type for harm values and V the type for vulnerability values, both equipped with preorders \leq_V and \leq_W . The 'reward' in the current scenario replaces 'harm', and maximized instead of minimized. Similarly, the 'total reward' computed as the measure of the \oplus -sum of the rewards along possible trajectories mirrors the 'vulnerability' which does the same for 'harm'. It may make sense to generalize Val into two different types in settings were a single-step reward and a total aggregated reward fall into different types and preorders as well.

Exercise 7.2:

What is the type of \leq_l in the definition of OptPolicySeq? Define \leq_l in terms of \leq .

The type for \leq_l is the pointwise inequality between functions $(x : X t) \rightarrow Val$. Here's its definition in terms of \leq :

```
_\leql_ : {t : Nat} \to (X t \to Val) \to (X t \to Val) \to Set f \leql g = \forall x \to (f x \leq g x)
```

Exercise 7.3:

On the fly: How many trajectories are in trj $[p_0, p_1] x_0$?

The number of possible XYSeq trajectories can be determined by the number of state trajectories, which are exactly 3:

```
[x_0, x_1^0, x_2^{0,0}]
[x_0, x_1^0, x_2^{0,1}]
[x_0, x_1^1, x_2^{1,0}]
```

Exercise 7.4:

Define ηSP , fmap_{SP} and >>=SP such that trj $[p_0, p_1] x_0$ yields the result of step₂.

We define fmapSP the same way as for fmapList, but we also append the probability coordinate. Similarly η SP is defined as the singleton but appending the probability p = 1. For >>=SP we postulate μ SP by replacing M by SP in the previous declaration of μ M:

```
open import Data.Float using (Float) renaming (_+_ to _+Float_; _*_ to _*Float_)
-- Val = R, but we use Float instead
           : Set
ValSP
ValSP = Float
-- Val = 0
OValSP : ValSP
0ValSP = 0.0
-- usual addition
\_\oplus SP\_ : ValSP \to ValSP \to ValSP
a \oplus SP b = a + Float b
\mathtt{SP} \quad : \ \mathtt{Set} \ \to \ \mathtt{Set}
SP X = List (X \times Float)
\mathsf{fmap}_{\mathsf{SP}} \; : \; \{ \texttt{A} \; \texttt{B} \; : \; \texttt{Set} \} \; \rightarrow \; (\texttt{A} \; \rightarrow \; \texttt{B}) \; \rightarrow \; \texttt{SP} \; \; \texttt{A} \; \rightarrow \; \texttt{SP} \; \; \texttt{B}
fmap_{SP} f [] = []
fmap_{SP} f ((x , p) :: xps) = (f x , p) :: (fmap_{SP} f xps)
-- Singleton equivalent, p = 1
\eta \mathrm{SP} : {X : Set} 	o X 	o SP X
\eta SP x = (x , 1.0) :: []
```

```
postulate \muSP : {X : Set} \to SP (SP X) \to SP X __>>=SP_ : {A B : Set} \to SP A \to (A \to SP B) \to SP B ma >>=SP f = \muSP (fmap<sub>SP</sub> f ma)
```

Exercise 7.5:

In $step_4$ we have applied a definition of the exp. value measure ev. Define ev consistently with $step_4$.

We define the expected value as the sum of the products of the state-probability pair:

```
-- measure = expected value ev : SP ValSP \rightarrow ValSP ev [] = 0ValSP ev ((x , p) :: xps) = (x *Float p) +Float (ev xps)
```

which is now consistent with $step_4$.

Exercise 7.6:

Is the computation correct? Check it and report eventual errors!

We elaborate and specify the intermediate steps:

$$\begin{split} r_0^0 * \alpha + r_1^{0,0} * \beta * \alpha + r_1^{0,1} * (1-\beta) * \alpha + r_0^1 * (1-\alpha) + r_1^{1,0} * (1-\alpha) \\ &= \left\{ step_6 : \left(r_0^0 + r_1^{0,0} * \beta + r_1^{0,1} * (1-\beta)\right) * \alpha + \left(r_0^1 + r_1^{1,0}\right) * (1-\alpha) \right\} = \\ \text{ev} \left[\left(r_0^0 + r_1^{0,0} * \beta + r_1^{0,1} * (1-\beta), \alpha\right), \left(r_0^1 + r_1^{1,0}, (1-\alpha)\right) \right] \\ &= \left\{ step_7 \text{ same as } step_6 \right\} = \\ \text{ev} \left[\left(r_0^0 + \text{ev} \left[\left(r_1^{0,0}, \beta\right), \left(r_1^{0,1}, 1-\beta\right) \right], \alpha\right), \left(r_0^1 + \text{ev} \left[\left(r_1^{1,0}, 1\right) \right], 1-\alpha \right) \right] \\ &= \left\{ definitions \text{ of } r_1^{0,0}, r_1^{0,1} \text{ and } r_1^{1,0} \right\} \\ \text{ev} \left[\left(r_0^0 + \text{ev} \left[\left(\text{reward } 1 \ x_1^0 \ y_1^0 \text{ (head } (Last \ x_2^{0,0})), \beta\right), \left(\text{reward } 1 \ x_1^0 \ y_1^0 \text{ (head } (Last \ x_2^{0,1})), 1-\alpha \right) \right] \\ &= \left\{ definition \text{ of sumR} \right\} \\ \text{ev} \left[\left(r_0^0 + \text{ev} \left[\left(\text{sumR} \left(\left(x_1^0, y_1^0 \right) \parallel Last \ x_2^{0,0} \right), \beta\right), \left(\text{sumR} \left(\left(x_1^0, y_1^0 \right) \parallel Last \ x_2^{0,1} \right), 1-\beta \right) \right], \alpha \right), \\ \left(r_0^1 + \text{ev} \left[\left(\text{sumR} \left(\left(x_1^0, y_1^0 \right) \parallel Last \ x_2^{0,0} \right), \beta\right), \left(\text{sumR} \left(\left(x_1^0, y_1^0 \right) \parallel Last \ x_2^{0,1} \right), 1-\beta \right) \right], \alpha \right), \\ \left(r_0^1 + \text{ev} \left[\left(\text{sumR} \left(\left(x_1^1, y_1^1 \right) \parallel Last \ x_2^{0,0} \right), \beta\right), \left(\left(\left(x_1^0, y_1^0 \right) \parallel Last \ x_2^{0,1} \right), 1-\beta \right) \right], \alpha \right), \\ \left(r_0^1 + \text{ev} \left(\text{fmapsp sumR} \left[\left(\left(\left(\left(x_1^1, y_1^1 \right) \parallel Last \ x_2^{0,0} \right), \beta\right), \left(\left(\left(\left(x_1^0, y_1^0 \right) \parallel Last \ x_2^{0,1} \right), 1-\beta \right) \right) \right], \alpha \right), \\ \left(r_0^1 + \text{ev} \left(\text{fmapsp sumR} \left[\left(\left(\left(\left(x_1^1, y_1^1 \right) \parallel Last \ x_2^{0,0} \right), \beta\right), \left(\left(\left(\left(\left(x_1^0, y_1^0 \right) \parallel Last \ x_2^{0,1} \right), 1-\beta \right) \right) \right), \alpha \right), \\ \left(r_0^1 + \text{ev} \left(\text{fmapsp sumR} \left[\left(\left(\left(\left(\left(x_1^1, y_1^1 \right) \parallel Last \ x_2^{0,0} \right), \beta\right), \left(\left(\left(\left(\left(x_1^0, y_1^0 \right) \parallel Last \ x_2^{0,1} \right), 1-\beta \right) \right) \right), \alpha \right), \right. \\ \left(r_0^1 + \text{ev} \left(\text{fmapsp sumR} \left(\text{tr} \left(\left(\left(\left(\left(x_1^0, y_1^0 \right) \parallel Last \ x_2^{0,0} \right), \beta\right), \left(\left(\left(\left(\left(\left(x_1^0, y_1^0 \right) \parallel Last \ x_2^{0,1} \right), 1-\beta \right) \right) \right), \alpha \right), \right. \\ \left(r_0^1 + \text{ev} \left(\text{fmapsp sumR} \left(\text{tr} \left(\left(\left(\left(\left(\left(\left(\left(x_1^0, y_1^0 \parallel Last \ x_2^{0,0} \right), \gamma\right), r_0^{0,1} \right), r_0^{0,1} \right), \left. \left($$

Exercise 7.7:

Redo the computation for the non-deterministic case with the canonical monadic operations for List and with measure = sum. Do you obtain the same computational pattern?

Intuitively, both should behave in the same manner since in the stochastic case, the measure = ev is obtained by first converting the simple distribution to a simple list by multiplying the state-probability pairs and then adding them in the same way that the measure = sum would do when there's no probabilities involved in the first place. Hence, the cases $(M = \mathsf{SP}, \text{measure} = \mathsf{ev})$ and $(M = \mathsf{List}, \text{measure} = \mathsf{sum})$ should yield exactly the same pattern.

Exercise 7.8:

end

```
Prove Bellman's equation for the "plain" deterministic case using
   postulate Lemma7 : (t n : Nat) 
ightarrow (p : Policy t) 
ightarrow
                     (ps : PolicySeq (suc t) n) 
ightarrow (x : X t) 
ightarrow
                     sumRId (trjId (p :: ps) x ) \equiv
                     rewardId t x (p x ) (nextId t x (p x )) \oplusId
                     (valId ps (nextId t x (p x)))
   Error solved, \oplusIId (\oplusId extended to functions) had to be defined:
   _\opluslId_ : {t : Nat} 	o (X t 	o ValId) 	o (X t 	o ValId) 	o (X t 	o ValId)
  f \oplus lId g = (\lambda x \rightarrow f x \oplus Id g x)
The proof is as follows:
  \texttt{BellmanEq} \; : \; (\texttt{t n} \; : \; \texttt{Nat}) \; \rightarrow \; (\texttt{p} \; : \; \texttt{Policy t}) \; \rightarrow \; (\texttt{ps} \; : \; \texttt{PolicySeq} \; (\texttt{suc t}) \; \texttt{n})

ightarrow (x : X t) 
ightarrow
                valId (p :: ps) x \equiv
                measureId (fmapId (rewardId t x (p x) \opluslId valId ps) (nextId t x (p x)))
   BellmanEq t n p Nil x =
     begin
        valId (p :: Nil) x
        sumRId (trjId (p :: Nil) x)
     =\langle Lemma7 t n p Nil x \rangle
        rewardId t x (p x ) (nextId t x (p x )) \oplusId (valId Nil (nextId t x (p x)))
     =\langle\rangle -- def of \opluslId
        (rewardId t x (p x) \opluslId valId Nil) (nextId t x (p x))
        measureId (fmapId (rewardId t x (p x) \opluslId valId Nil) (nextId t x (p x)))
     end
  BellmanEq t n p1 (p0 :: ps) x =
     begin
        valId (p1 :: (p0 :: ps)) x
        sumRId (trjId (p1 :: (p0 :: ps)) x)
     =\langle Lemma7 t n p1 (p0 :: ps) x \rangle
        rewardId t x (p1 x) (nextId t x (p1 x )) \oplusId
        (valId (p0 :: ps) (nextId t x (p1 x)))
     =\langle\rangle
        (rewardId t x (p1 x) \oplus1Id valId (p0 :: ps)) (nextId t x (p1 x))
        measureId (fmapId (rewardId t x (p1 x) \oplus1Id valId (p0 :: ps))
        (nextId t x (p1 x)))
```

Exercise 7.9:

```
Implement
```

```
\mathtt{optExt} \;:\; \{\mathtt{t}\;\; \mathtt{n} \;:\; \mathtt{Nat}\} \;\to\; \mathtt{PolicySeq} \;\; (\mathtt{suc}\;\; \mathtt{t}) \;\; \mathtt{n} \;\to\; \mathtt{Policy} \;\; \mathtt{t}
```

applying

We add the extra postulate finiteY in order to create an element of type Finite (Y t x):

```
postulate finiteY : {t : Nat} (x : X t) \rightarrow Finite (Y t x) optExt : {t n : Nat} \rightarrow PolicySeq (suc t) n \rightarrow Policy t optExt {t} ps x = argmax (\lambda y \rightarrow measure (fmapM (reward t x y \oplusl vallBell ps) (next t x y))) (toList (finiteY x))
```

Exercise 7.10:

Formulate minimal requirements on toList, max and argmax for optExt to satisfy

```
\texttt{optExtSpec} \; : \; \{\texttt{t} \; \texttt{n} \; : \; \texttt{Nat}\} \; \rightarrow \; (\texttt{ps} \; : \; \texttt{PolicySeq} \; (\texttt{suc} \; \texttt{t}) \; \; \texttt{n}) \; \rightarrow \; \texttt{OptExt} \; \; \texttt{ps} \; (\texttt{optExt} \; \; \texttt{ps})
```

Small type-checking obstacle: how to combine inequalities and equalities in equational reasoning? I've defined

but there's a missing link (an Either probably?) to the \equiv counterparts in the proof. Here's the reasoning but it doesn't type check.

```
postulate maxSpec : {t : Nat} \rightarrow {x : X t} \rightarrow (y : Y t x)

ightarrow (f : Y t x 
ightarrow Val) 
ightarrow List (Y t x)
                           \rightarrow f y \leq max f (toList (finiteY x))
\texttt{postulate argmaxSpec} \; : \; \{\texttt{t} \; : \; \texttt{Nat}\} \; \rightarrow \; \{\texttt{x} \; : \; \texttt{X} \; \; \texttt{t}\} \; \rightarrow \; (\texttt{f} \; : \; \texttt{Y} \; \; \texttt{t} \; \; \texttt{x} \; \rightarrow \; \texttt{Val}) \; \rightarrow \; \texttt{List} \; \; (\texttt{Y} \; \; \texttt{t} \; \; \texttt{x})
                           \rightarrow f (argmax f (toList (finiteY x))) \equiv max f (toList (finiteY x))
\texttt{optExtSpec} \; : \; \texttt{\{t n : Nat\}} \; \rightarrow \; \texttt{(ps : PolicySeq (suc t) n)} \; \rightarrow \; \texttt{OptExt ps (optExt ps)}
optExtSpec \{t\} \{n\} ps p'x =
     begin \le
            vallBell (p' :: ps) x
            measure (fmapM (reward t x (p' x) \oplus1 vallBell ps) (next t x (p' x)))
      \leq \langle maxSpec (p'x) (\lambda y 	o measure (fmapM (reward t x y \oplusl vallBell ps)
      (next t x y))) (toList (finiteY x)) >
            \max (\lambda y 	o measure (fmapM (reward t x y \oplusl vallBell ps) (next t x y)))
            (toList (finiteY x))
     =\langle argmaxSpec (\lambda y 	o measure (fmapM (reward t x y \oplusl vallBell ps) (next t x y)))
      (toList (finiteY x)) >
            measure (fmapM (reward t x (optExt \{t\} ps x) \oplus 1 vallBell ps)
            (next t x (optExt {t} ps x)))
     \leq \langle \rangle
            vallBell (optExt ps :: ps) x
      end<
```

Exercise 7.11:

Postulate measureMon, plusMon and implement Bellman. We first define OptPolicySeqBell specific to valBell (val computed defined in order to perform backwards induction):

To implement Bellman we prove that for every policy p' and policy sequence ps' it holds that

```
valBell (p' :: ps') \leq_l valBell (p :: ps).
```

The equational reasoning goes as follows (no type-checking has been attempted due to the previous issue of combining inequalities and equalities in the same proof):

```
{OptPolicySeqBell ps}
val ps' \leq_l val ps
{def}
\forall \; \bar{\textbf{x}} \rightarrow \; \text{val ps} \; \bar{\textbf{x}} \leq \; \text{val ps} \; \bar{\textbf{x}}
\{(\texttt{reward t x (p' x) } \bar{\texttt{x}} \leq \texttt{reward t x (p' x) } \bar{\texttt{x}}) + \texttt{plusMon postulate}\}
\forall \; \bar{x} 
ightarrow \; \text{reward t x (p' x)} \; \bar{x} \; \oplus \; \text{val ps'} \; \bar{x} \; \leq \; \text{reward t x (p' x)} \; \bar{x} \; \oplus \; \text{val ps'} \; \bar{x}
{def}
\Leftrightarrow
reward t x (p' x) \oplus_l val ps' \leq_l reward t x (p' x) \oplus_l val ps'
{measureMon postulate}
\forall mx' 	o measure (fmapM (reward t x (p' x) \oplus_l vallBell ps') (mx'))
         measure (fmapM (reward t x (p' x) \oplus_l vallBell ps) (mx'))
\forall x \rightarrow measure (fmapM (reward t x (p' x)) \oplus_l vallBell ps') (next t x (p' x)))
         measure (fmapM (reward t x (p' x) \oplus_l vallBell ps) (next t x (p' x)))
{def}
\Leftrightarrow
\forall x \rightarrow valBell (p' :: ps') x \leq valBell (p' :: ps) x
valBell (p' :: ps') \leq_l valBell (p' :: ps)
{OptExt ps p = \forall p' \rightarrow valBell (p' :: ps) \leq_l valBell (p :: ps)}
valBell (p' :: ps') \leq_l valBell (p :: ps)
```

Exercise 7.12:

Implement biOptVal by induction on n.

TODO

Exercise 7.13:

There are also more "practical" limitations which ones come up to your mind?

Even restricting the domain of policies to the "viable" and "reachable" states, this doesn't fix the computational intractability of backwards induction. Look up tables may be integrated at the cost of not being able to machine-check correctness proofs ("SEQUENTIAL DECISION PROBLEMS, DEPENDENT TYPES AND GENERIC SOLUTIONS").
